## Volatility Smile / Skew

- 理论中的 U-Shaped 波动率曲线
- Reverse Skew (Put Skew) & Forward Skew (Call Skew)

Assumptions of the Black-Scholes-Merton Model: 股价的回报呈现对数正态分布

- *The underlying price follows a lognormal probability distribution as it evolves through time.*

A lognormal probability distribution is one in which the log return is normally distributed. For example, if a stock moves from 100 to 110, the return is 10% but the log return is  $\ln(1.10) = 0.0953$  or 9.53%. This assumption is reasonable for most assets that offer options. Additionally, the variance of the return is assumed to be constant for the life of the option.

- *Interest rates remain constant and known.* 利率被假设为恒定不变

The model uses the risk-free rate to represent this constant and known rate. During periods of rapidly changing interest rates, these 30 day rates are often subject to change, thereby violating one of the assumptions of the model. The assumption also becomes a problem for pricing options on bonds and interest rates.

- *The volatility of the underlying asset is known and constant.*

The volatility of the underlying is specified in the form of the standard deviation of the log return. This is the most critical assumption. 股价的（未来）波动率被假定为恒定不变

- *No transaction costs or taxes.*

- *No cash flows on the underlying.* 不存在现金股利

- *European exercise terms are used.* 合约需要持有到期

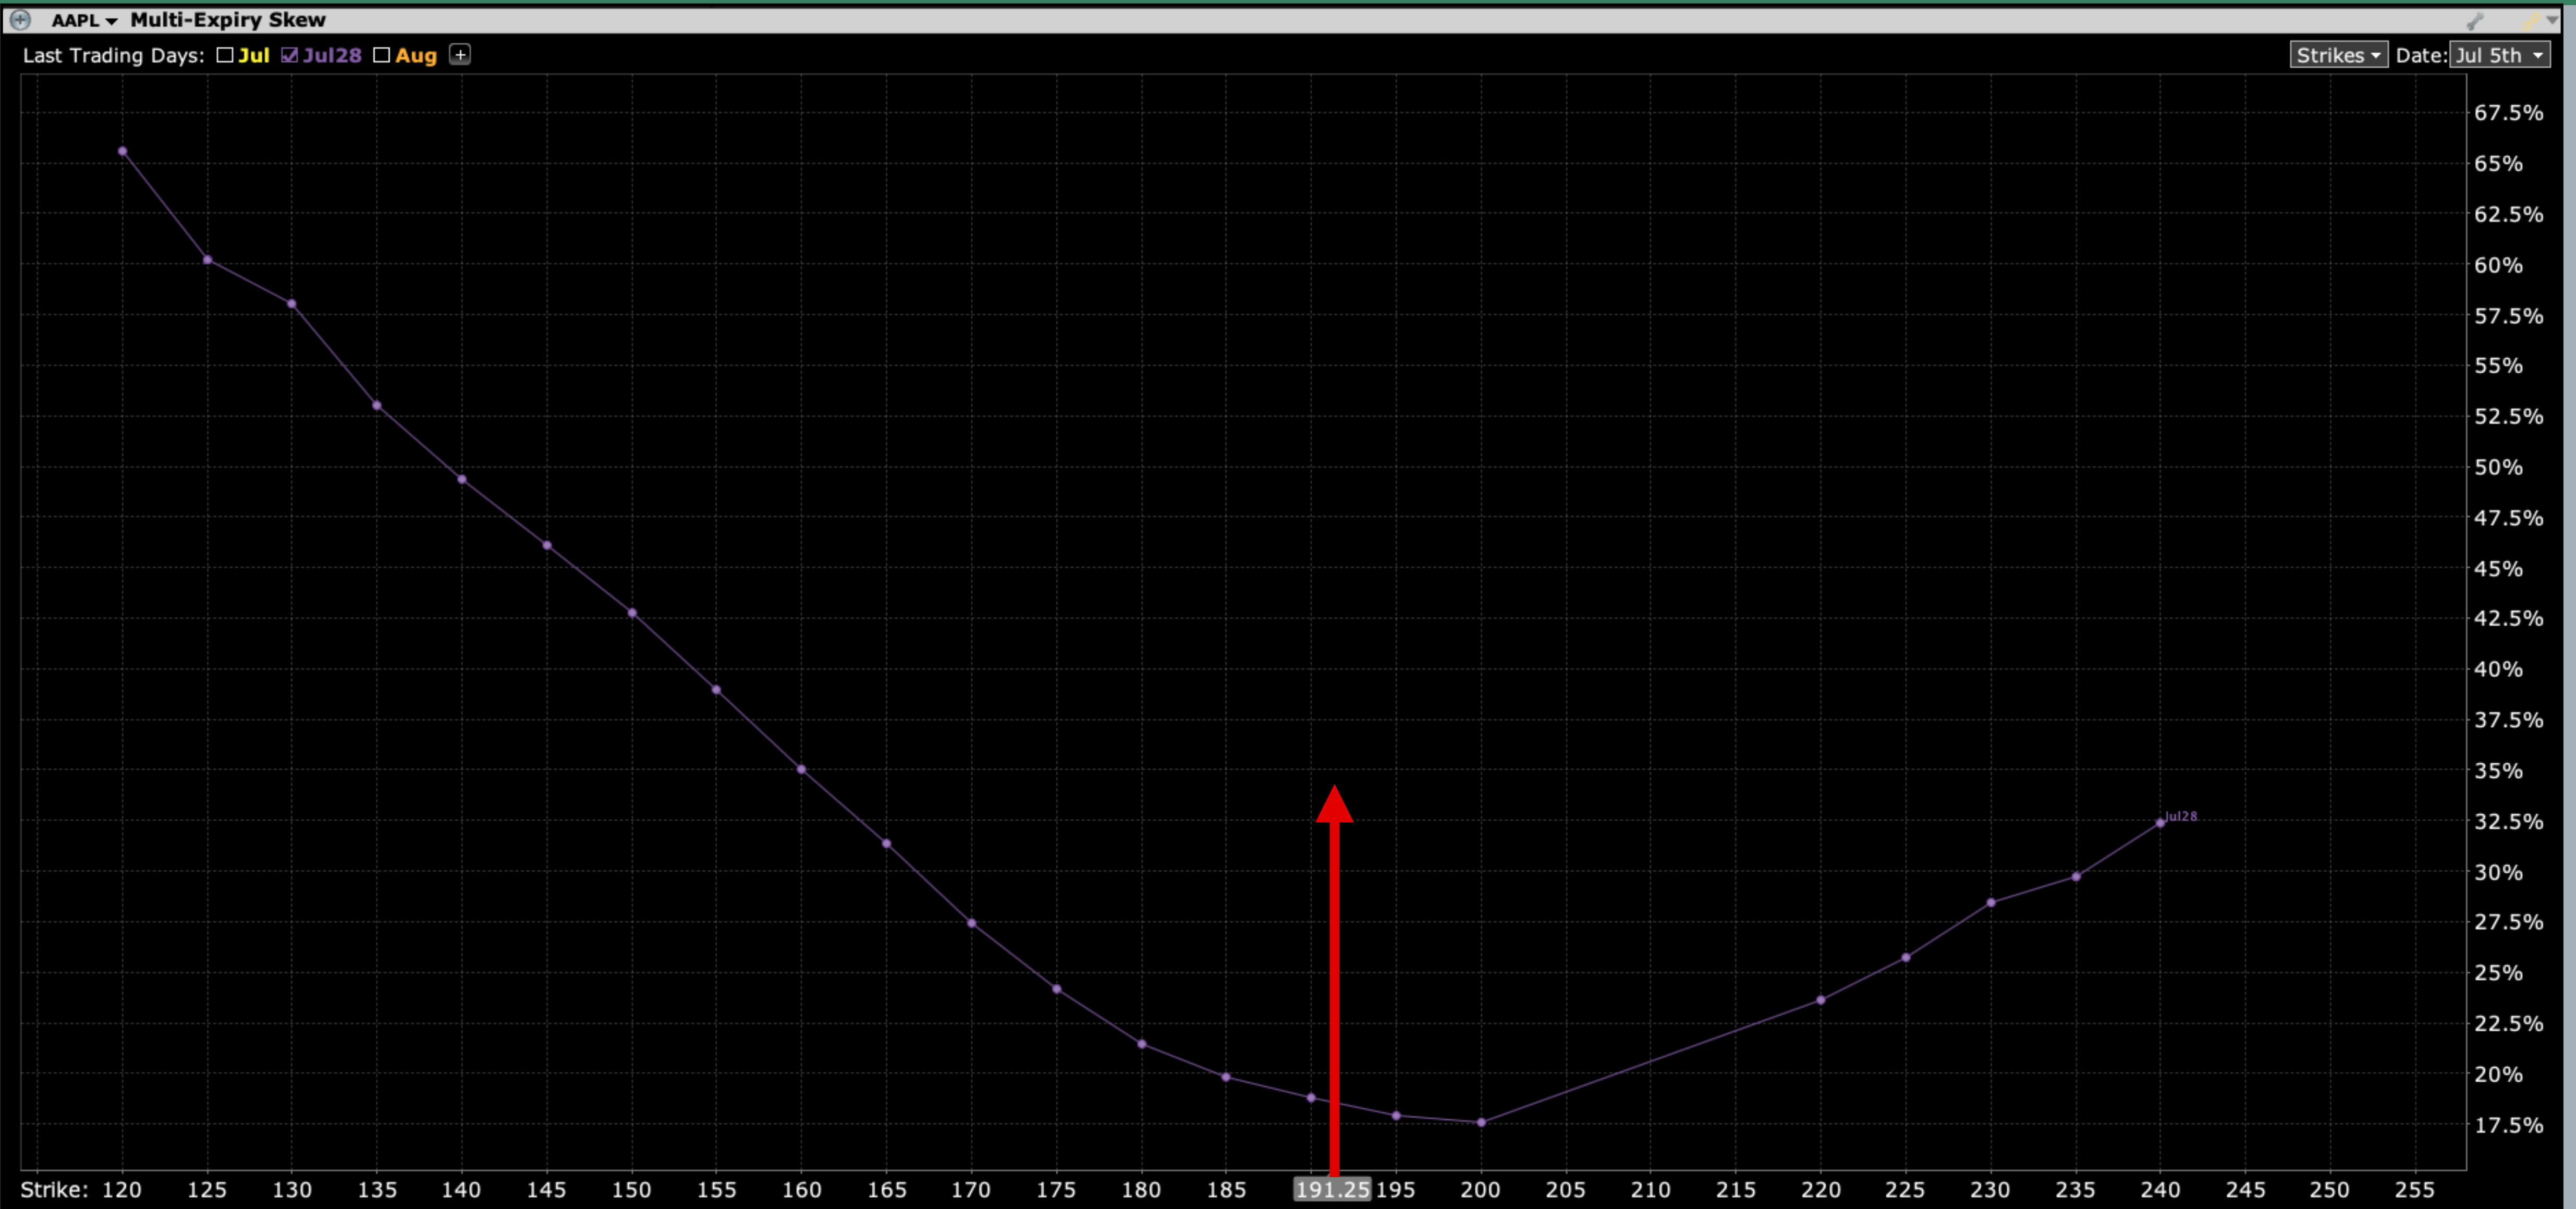

This limitation is not a major concern because very few calls are ever exercised before the last few days of their life. This is true because when you exercise a call early, you forfeit the remaining time value on the call and collect the intrinsic value. Towards the end of the life of a call, the remaining time value is very small, but the intrinsic value is the same.
